EFFICIENT FIBER-SEMICONDUCTOR TUNABLE LASER SOURCE

Reference to Pending Prior Patent Application

This patent application claims benefit of pending prior U.S. Provisional Patent Application Serial No. 60/220,070, filed 07/21/00 by Daryoosh Vakhshoori et al. for Efficient Fiber-Semiconductor Tunable Laser Source, which patent application is hereby incorporated herein by reference.

Field Of The Invention

This invention relates to tunable laser sources and more particularly to laser sources comprising optically pumped tunable vertical cavity surface emitting diode lasers and optical fiber amplifiers.

Background Of The invention

Single mode optical fibers doped with rare-earth elements are well known for their high efficiency. However, lasers made with doped fibers as gain medium bear challenges in cavity stabilization. Usually a

sophisticated and complex scheme has to be employed in order to obtain a stable and high quality spectral output. A vertical cavity surface emitting laser (VCSEL) with a movable mirror has the advantage of providing a wide tuning range with high quality spectral output, but the efficiency of the VCSEL tends to be limited due to low gain of the cavity. The maximum possible power from an optically pumped VCSEL is further restricted by the difficulty of dissipating heat, which tends to limit full use of the increasingly high power available from single mode pump diodes.

Summary Of The Invention

The primary object of the invention is to provide an efficient, high power and high quality tunable laser source.

A further object is to extend the capabilities of optically pumped tunable vertical cavity surface emitting diode lasers.

Still another object is utilize a doped fiber amplifier to increase the power output of an optically pumped VCSEL.

These and other objects are achieved by providing a laser source that comprises in combination a VSCEL, a doped optical gain fiber, a pump laser, and means coupling said pump laser, said VCSEL and said fiber whereby said VCSEL and said fiber are optically pumped by the output of said pump laser and the output of said vertical cavity surface emitting laser is injected into said fiber and is amplified in said fiber by the output of said pump laser. Other features and advantages of the invention will be made clear by the following detailed description which is to be considered together with the accompanying drawings.

The Drawings

Figure 1 illustrates an amplified tunable VCSEL constituting a first and preferred embodiment of the invention;

Figure 2 illustrates a second embodiment of the invention;

Figure 3 illustrates a third embodiment of the invention; and

5 Figure 4 illustrates a fourth embodiment of the
invention.

In the drawings, like components are identified by like numerals.

A Specific Description Of The Invention

The several embodiments hereinafter described combine the advantages of a VCSEL with the advantages of doped optical gain fibers, thereby providing economical, efficient, high power and high quality tunable laser sources.

20 an optical isolator 6. The latter directs beam 4 at a
diachronic beam splitter 10 which effectively

subdivides the beam power, with part of beam 4 being reflected as a beam 12 with wavelength λ_1 and the remainder of beam 4 passing through the beam splitter as laser beam 14 with wavelength λ_1 . The beam 12 is directed by the beam splitter 10 into a VCSEL represented schematically at 16. Various forms of VCSELs may be used in practicing this invention. Preferably the VCSEL has a structure like one of those described in co-pending U.S. Patent Application No. 09/281,407, filed March 30, 1999 by Daryoosh Vakhahoori et al. for "Optically Pumped Tunable Surface Emitting Lasers", and U. S. Patent Application No. 09/105,399, filed June 26, 1998 by Tayebati et al. for "Microelectromechanically Tunable, Confocal, Vertical Cavity Surface Emitting Laser and Fabry-Perot Filter", which applications are incorporated herein by reference. Still other forms of VCSELs known to persons skilled in the art may be used in practicing the invention.

The VCSEL 16 has a fixed mirror 18 and a movable cavity mirror 20 at opposite ends of a cavity 21, plus

electrodes (not shown) for electrically tuning the device. In the VCSEL, wavelength tuning is achieved by moving mirror 20 so as to vary the laser cavity length. In Fig. 1, beam splitter 10 is located along the optical axis of the VCSEL as shown, so as to maximize the optical coupling of beam 12 with the VCSEL and avoid the need for intervening optics. The 5 pump laser beam 12 at wavelength λ_1 passes into the cavity via mirror 20 to optically pump the VCSEL and cause the latter to produce an output beam 24 at wavelength λ_2 that exits via mirror 20. The splitter 10 is designed and disposed so that it will pass VCSEL 10 laser beam 24, while at the same time splitting pump 15 laser beam 4 as described. In this connection, it is to be noted that the VCSEL output beam 24 is polarized as a result of well controlled birefringence of the VCSEL. The VCSEL laser output beam 24 passes from splitter 10 via an optical isolator 26 into a polarization dependent high reflector/beam splitter 20 represented schematically at 28 which is interposed between a diachronic mirror 30 and an output focusing

lens 32. Splitter 28 is adapted to reflect the polarized VCSEL beam 24 to mirror 30. The latter is adapted to pass VCSEL beam 24 to a focusing lens 38 and also to reflect pump laser beam 14 as hereinafter described.

The laser apparatus of Fig. 1 further includes a highly reflective mirror 34 which is disposed to receive λ_1 wavelength beam 14 and to reflect it to diachronic mirror 30. The latter in turn reflects beam 14 to focusing lens 38. The latter transmits VCSEL beam 24 and pump laser beam 14 into one end of a doped high gain optical fiber 40. The opposite end of the fiber is coupled to a Faraday rotator mirror 42 which reflects the VCSEL beam back along the fiber toward beam splitter 28 and also serves to rotate the VCSEL beam polarization 90 degrees so that it can pass through beam splitter 28 to output lens 32.

Operation of the laser system of Fig. 1 is as follows. The VCSEL 16 responds to the pump laser beam 12 at wavelength λ_1 by generating VCSEL laser beam 24 at wavelength λ_2 . The VCSEL laser beam passes through

the beam splitter 10 and isolator 26 to beam splitter 28, which then reflects the beam to diachronic mirror 30. The VCSEL beam passes through mirror 30 and is transmitted by the focusing lens 38 into the high gain fiber 40. The pump laser is chosen with an output beam wavelength λ_1 that will effectively pump the doped gain fiber 40, which typically has a relatively narrow absorption band. In this connection it is to be noted that the VCSEL, being made from a semiconductor, has a wide tolerance for the wavelength of the pump laser in relation to its response to the pump laser beam.

The illustrated apparatus of Fig. 1 experiences maximum amplification due to the fact that the laser beam output of the VCSEL essentially has a double transit along the length of high gain fiber 40. As noted above, the VCSEL beam 24 has a selected polarization as it passes from splitter 10 that allows it to be reflected by beam splitter 28. However, the Faraday rotator mirror 42 rotates the polarization of the VCSEL output beam 90 degrees, with the result that on its return transit along gain fiber 40 the beam

passes through splitter 28 and is extracted from the system by passing through output focusing lens 32 to an output port. By way of example but not limitation, the output port may comprise an optical fiber 50.

5 Figure 2 illustrates an alternative embodiment of the invention. In this arrangement, the beam splitter 28 is omitted and the VCSEL output beam 24 passes directly to diachronic mirror 30. Beam 24 passes through mirror 30 to focusing lens 38. Additionally a highly reflective mirror 52 is positioned to reflect pump laser beam 14 received from mirror 34 and to direct it to diachronic mirror 30 which is positioned so as to reflect beam 14 to focusing lens 38. The latter directs the combined beams 14 and 24 into one end of a single mode high gain fiber 40A which also serves as the output line.

10 Operation of the embodiment of Figure 2 is as follows. The VCSEL output beam 24 at wavelength λ_2 is transmitted via the isolator 26 to diachronic mirror 30 which passes it into the high gain fiber 40A. 20 Simultaneously the pump laser beam 14 at a wavelength

λ_1 is injected into the high gain fiber via reflections by mirrors 34, 52 and 30 to provide amplification for the VCSEL output beam. As a result the λ_2 wavelength output beam that exits the remote end of the high gain fiber line 40A has a greater power than the original output beam of the VCSEL.

Figure 3 illustrates still another embodiment of the invention. In this case pump laser 2, a collimating lens 8A, isolator 6 and diachronic beam splitter 10 are disposed so as to optically pump the VCSEL 16 via transit through its fixed mirror 18. Beam splitter 10 splits the λ_1 wavelength pump laser beam 4 into beams 12 and 14. The pump laser beam 14 is injected into the VCSEL via the stationary mirror 18, causing the VCSEL to produce a laser output beam 24 with wavelength λ_2 . That beam passes through diachronic mirror 30 to a focusing lens 38 which couples the beam into one end of single mode optical gain fiber 40A which also serves as the output line.

The system of Fig. 3 also includes mirrors 34 and 52 which are arranged to intercept, reflect and direct

pump laser beam 12 to the diachronic chronic mirror 30 at an angle such that it will be reflected to focusing lens 38 and directed thereby into the proximal end of gain fiber 40A. Pump laser beam 12 acts on high gain fiber 40A to amplify the power of the VCSEL beam injected into fiber 40A.

Figure 4 shows a fourth embodiment of the invention. In this case a single mode high gain fiber 40B is coupled at one end to an external wavelength division multiplexer 56. The near end of the fiber 40B is disposed so as to be optically coupled to VCSEL 16, whereby (a) the VCSEL may be pumped by a pump laser beam as hereinafter described and (b) the λ_2 wavelength output beam of the VCSEL is injected into the near end of the gain fiber. The manner in which the fiber 40B is optically coupled for injection therein of the laser output of the VCSEL is not critical to the invention; therefore, optical coupling of fiber 40B to the VCSEL may be accomplished in various ways known to persons skilled in the art without departing from the invention. A pump laser 2

is provided for producing a pump laser beam at wavelength λ_1 , and injection of that pump laser beam into fiber 40B is accomplished via a wavelength division multiplexer 56 which is coupled to the outer end of gain fiber 40B. The exact form of the multiplexer is not critical to the invention and various forms of multiplexers known to persons skilled in the art may be used in practicing the embodiment shown in Figure 4. The multiplexer serves several purposes. It injects the pump laser beam 4 into the high gain fiber 40B, whereby to provide amplification for the VCSEL's laser output. It also serves as the system's output port for the VCSEL's amplified laser beam, whereby that beam may be coupled to another device or system, e.g., via an optical fiber 60.

Operation of the system of Figure 4 is as follows. The pump laser 2 injects a pump laser beam with a selected wavelength λ_1 into fiber 40B via the multiplexer 56. The injected pump laser beam is injected via the fiber into the VCSEL, causing the latter to generate a laser output at a wavelength λ_2

which then travels along the fiber to the output port of the multiplexer. As the output from the VCSEL travels to the multiplexer, it is amplified by the counter-propagating pump beam in the gain fiber.

5 Consequently the power level of the VCSEL output appearing at the output port of the multiplexer 56 is substantially greater than that of the VCSEL beam that is injected into the near end of the fiber. The amplified VCSEL beam that exits the output port of the multiplexer 56 may be coupled to an external optical system for use, e.g., to an optical communications network.

12
13
14
15
The configuration of Figure 4 offers the advantage of simplicity and high amplification relative to the co-propagating configuration of Figures 2 and 3. The maximum amplification of the embodiment of Figure 4 is restricted by the feedback between the VCSEL and the wavelength division multiplexer, which must be kept very low to prevent lasing from the fiber amplifier.

The invention hereinabove described and
illustrated offers the advantage of providing an
efficient tunable laser source combined with the
advantages of a VCSEL and a fiber amplifier, with the
5 result that laser sources as provided by this
invention have utility in optical data and
communication equipment and networks.

The present invention may also be practiced
otherwise than as herein described and illustrated.
For example, use of the optical isolators 6 and 26,
which serve to suppress optical interference between
the components, is preferred but is not essential to
the invention. Additionally the optics coupling the
VCSEL laser, pump laser and high gain fiber may be
varied in various ways without departing from the
essence of the invention. It is understood also that
the pump lasers with outputs of different wavelengths
values may be used in practicing the invention,
provided, however, that they are suitable for
adequately optically pumping the VCSELs. The
20 injection of the pump beam of wavelength λ_1 to the

VCSEL and the output of the VCSEL at wavelength λ_2 may be coupled via various forms depending on the design of the cavity mirrors.

The invention is susceptible of still other modifications that will be obvious to persons skilled in the art from the foregoing description and the drawings.
